Abstract: The Global Yield Gap Atlas project (GYGA - <http://yieldgap.org>) has undertaken a yield gap assessment following the protocol recommended by van Ittersum et al. (2013). One part of the activities consists of collecting and processing weather data as an input for crop simulation models in sub-Saharan African countries including Kenya. This publication covers daily weather data for 12 locations in Kenya for the years 1998-2012. The project looked for good quality weather data in areas where crops are pre-dominantly grown. As locations with good public weather data are sparse in Africa, the project developed a method to generate bias corrected weather data from a combination of observed data and other external weather data. The bias corrected weather data consist of daily TRMM rain data and NASA POWER Tmax, Tmin, and Tdew data. These data are corrected based on calibrations with short-term (<10 years) observed weather data.

Keywords: Kenya; weather data; crop simulation model; yield gap; crop yield; yield potential

1 ORIGINAL PURPOSE: The Global Yield Gap Atlas calculates yield gaps for the major food crops. The project uses a bottom-up approach to build on local practices and local knowledge on agronomic systems. In every investigated country the project seeks collaboration with agronomists and other local experts. Yield gaps (Yg) are estimated by the difference between yield potential (Yp) without limitations due to water or other abiotic and biotic stresses (the most relevant benchmark for irrigated systems), or water-limited yield potential (Yw) as the benchmark for rainfed systems, and actual crop yields (Ya). Eco-physiological crop simulation models are used to estimate Yp, Yw, and crop water availability to account for the influence of climate, soil-type and length of growing season as determined by climate, cultivar and dominant cropping systems at each location. In many parts of the world with sub-tropical and tropical climates, farmers grow two or three crops per year on the same field. In these regions farmers strive to optimize productivity of the entire cropping system rather than yield of a single crop to maximize returns to labour, land and time. Therefore, estimates of Yp, Yw, and WP for a given crop in those systems must account for actual length of growing season as constrained by the cropping system. The bottom-up approach of the [GYGA protocol](#) allows use of actual location-specific data on current cropping systems, soil type, and long-term weather data from selected reference weather stations (RWS) so that results can be validated and improved upon as quality of such data improves and becomes available in major crop-producing regions worldwide. Where such data are of poor quality or not available, the GYGA utilizes the best existing data, or proxy data, with the goal of improving upon these data over time. As locations with good public weather data are sparse in Africa, the project developed a method to generate long term daily weather data from a combination of observed data and other external weather data (Van Wart et al. 2015). A detailed description of the method can be found at <http://www.yieldgap.org/methods-weather-data>.

2 MEASURED DATA: For all locations short term observed weather data are available from the Kenya Meteorological Department. The time span and the number of days with actual measured data differ between locations. For all of them the coverage of measured data starts in 1998 and ends in 2007 or 2008, with gaps in between for some or for all variables.

3 BIAS CORRECTED DAILY WEATHER DATA: The observed short-term (<10 years) weather data are used to calibrate data sources which do cover daily data for a long period: [TRMM](#) rainfall data and [NASA POWER](#) Tmax, Tmin, and Tdew data. The calibration step generates the data that get published here: bias corrected weather data generated from TRMM rainfall data and NASA POWER temperature data. The last step performed is some basic consistency checking. We checked rainfall ≥ 0 ; Tmin < Tmax. We checked annual rainfall sum > 300 mm.

4 DESCRIPTION OF PROVIDED DATA: This publication covers daily weather data for 12 locations in Kenya. They all are located in areas where crops are grown.

Time coverage: Daily data for the years 1998- 2012.

Locations: The locations are listed in Table 1.

Name	Longitude	Latitude	Elevation (m)
Dagoretti	36.45	-1.24	1798
Embu	37.58	-0.49	1350
Makindu	37.82	-2.29	1000
Meru	37.39	0.5	680
Kakamega	34.46	0.17	1530
Kericho	35.16	-0.22	2093
Nakuru	36.60	-0.16	1901
Thika	37.60	-1.1	1631
Eldoret	35.30	0.48	2120
Kisii	34.79	-0.68	1171
Kisumu	34.73	-0.07	1146
Kitale	34.96	0.97	1850

Variables: The variables provided are listed in Table 2.

Name	Description	Unit
Solar radiation	sum of incoming short wave global radiation	MJ/m2
MaxT	maximum temperature	°C
MinT	minimum temperature	°C
Mean RelHum	mean relative humidity	%
Precip	sum of precipitation	mm
Mean WndSpd	mean wind speed at 10 meter	m/s
Mean Tdew	mean dew point temperature	°C

Format: 13 CSV files, packed in a zip file. 1 CSV file contains overall metadata, the other 12 CSV files contain location information and the daily weather data for the 12 locations. The size of the zip file is less than 1 Mb. The unzipped size of the CSV files is 3.5 Mb.
